FiatECUScan.Project Summary/Abstract The overall objective of the proposed research is to create a technology enabling the transformation of microbial cell lysates into simple, inexpensive, bioactive peptides (BPs) for the treatment of a number of human diseases. Current peptide drug discovery processes are time consuming, costly, and yield far less active compounds than the natural ligands that are being targeted. Attempts to generate useful peptides directly from microbial cell lysates are compromised by the presence of toxic waste products. Moreover, it is generally accepted that the chemistry behind the process has yet to be developed. Cell-free expression of recombinant target proteins in aqueous-based expression/transcription/translation (E/T/T) systems, such as in vitro transcription/translation (IVTT), coupled with in vitro lysis (IVL) of the host cells has potential to become a powerful technology for the rapid production of recombinant proteins. The overall objective of this proposal is to develop an automated platform of enzymatic reactions for the in vitro lysis of host cells. In addition, a panel of innovative enzyme technologies will be developed to permit the rapid conversion of protein lysates into functional peptides. The resulting products will be a source of peptides in quantities and purity amenable to their use as research tools and as biologics for drug discovery and development. The ultimate goal is to provide a cost-effective means of producing peptides directly from a microbial cell lysate in quantities sufficient for potential use as therapeutic agents. To achieve this, the research team has already made considerable progress towards its overall objective. The specific aims of this proposal are: 1. Develop an automated platform for the lysis of *E. coli* and *S. cerevisiae* cells; 2. Develop an array of innovative enzyme technologies for use in the in vitro lysis of host cells; and 3. Establish proof of concept experiments demonstrating the ability to produce peptides from an aqueous-based E/T/T system. Relevance to Public Health: There are over 14,000 drugs currently on the market that are based on peptide activity, which accounts for half of all drugs currently in clinical trials. We have the potential to create a technology to rapidly produce peptides directly from microbial 2d92ce491b
