Twitty is a Java library that supports the design of intelligent agents. It's an adaptation of the wonderful Boo system for the Java programming language. Twitty is one of the very few Java projects to also support Boo as a complementary language. The idea behind Twitty is that it is based on a modular approach. So, there is a clear distinction between "domain-specific" and "application-specific" code. The domain-specific code defines the model of the agent. The application-specific code provides the logic for the agent. One can reuse this logic to define further agents. Example A very basic example of the Twitty library could be described as follows: For the design of the agent, we first have to define the model. In the example above, the model is the Lion, the Animal. This is very basic. We are also defining the behavior of the agent. We then start creating the agent. The agent is very simple. It will always look for food and move toward the point where it found the food. The example is very simple. In reality, an agent must have a proper behavior and needs to react to a certain situation. To enable this, the Twitty library provides a set of predefined actions and behaviors. Examples are to catch or throw an object. For example, one could let the agent catch a ball and throw it back. The agent could also put a box over the food. This will make the agent stay in the box for a while. When the agent detects that the box is open, it will get out of the box. Note: When the animal is not hungry, the agent will not move. It just doesn't do anything. Now, let us see the design. The abstract design of the agent in the example above is very simple. We started with a basic model. This was the Lion. The agent can only be a Lion. Then, we defined the behavior. The Lion can only go towards the food. The next step is to define the actions. In the example above, the agent can only be a Lion and needs to catch the food. In this case, we used the Twitty action named 'Catch' which returns a Boolean. This means that the agent will now do the action if the Boolean returns true. There are several predefined actions for the Animal. All are listed in the documentation. You can also define your own actions. Now, let's look at the application specific code. We defined the logic for the agent. The logic is very simple. The agent looks for food and then runs toward it. The agent has to stay in a box if it finds food. The only way the agent can get out of the box is to detect that it is open. Example A more complex example could look like this: This example is more complex. It defines
